

# Density and temperature measurements with SPICAM s stellar occultation

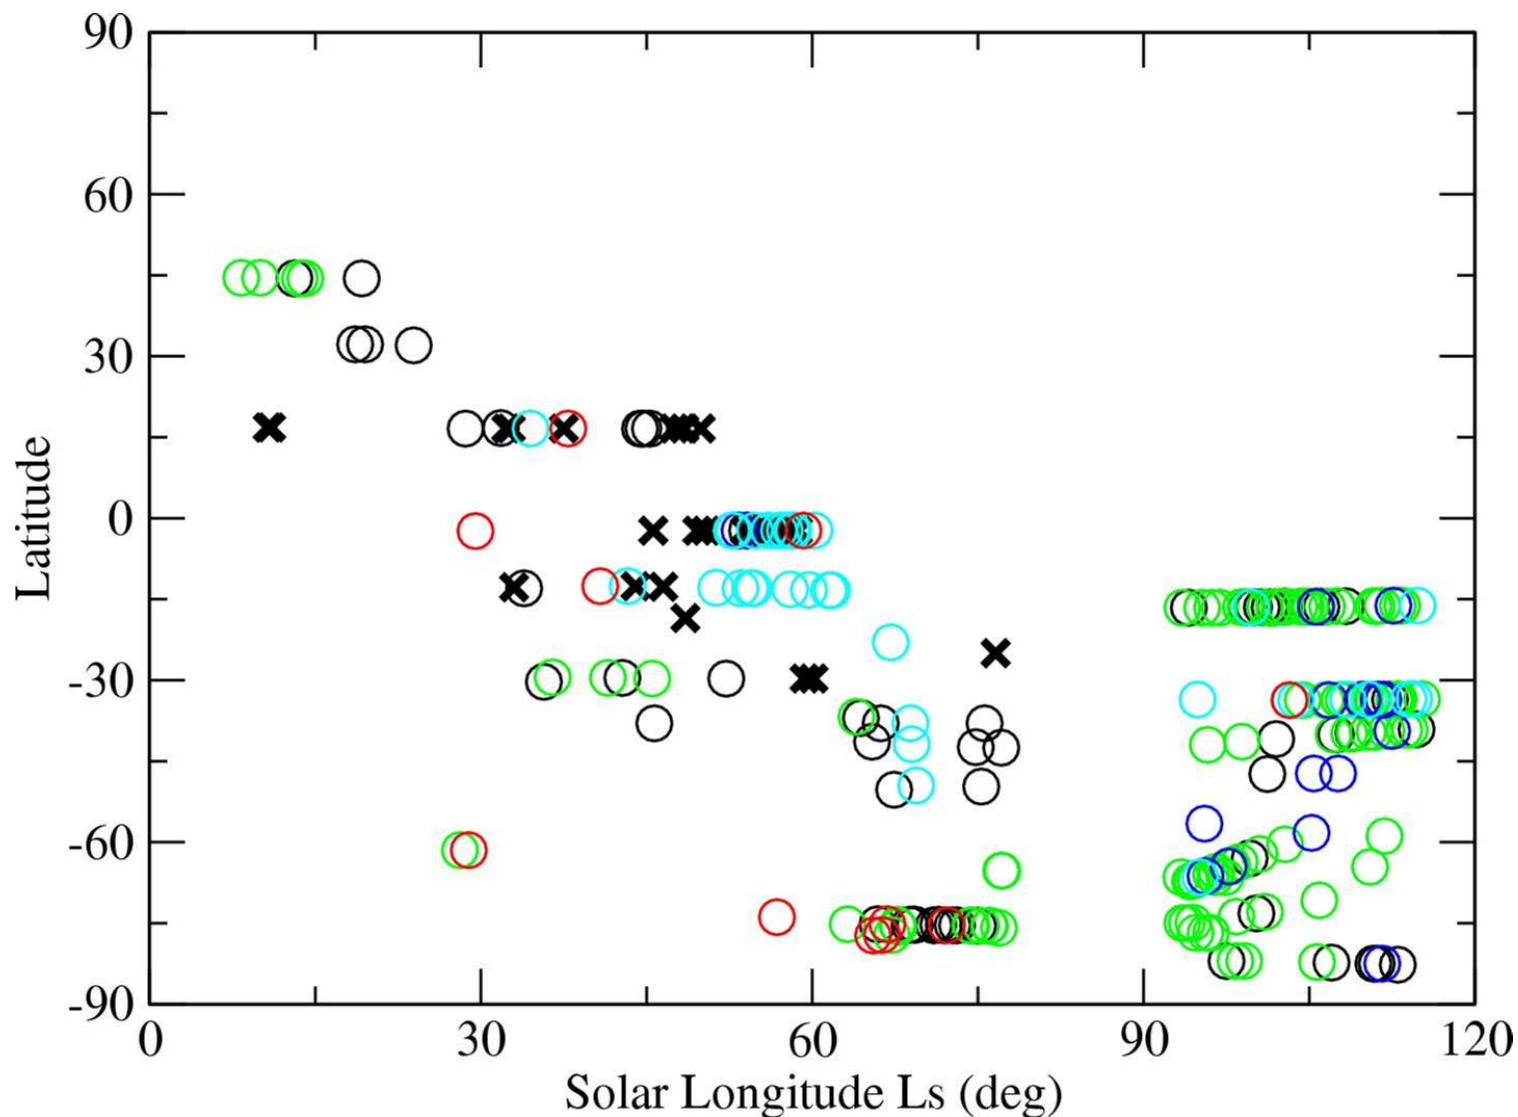

*François Forget, Eric Quemerais, Jean Loup  
Bertaux, Sébastien Lebonnois and the  
SPICAM team*

*LMD/SA,  
Institut Pierre Simon Laplace  
Paris*

# Solar / Stellar occultation

**Available occultations** : 238 usable observations  
Distribution in latitude and season

# Available occultations : 238 usable observations

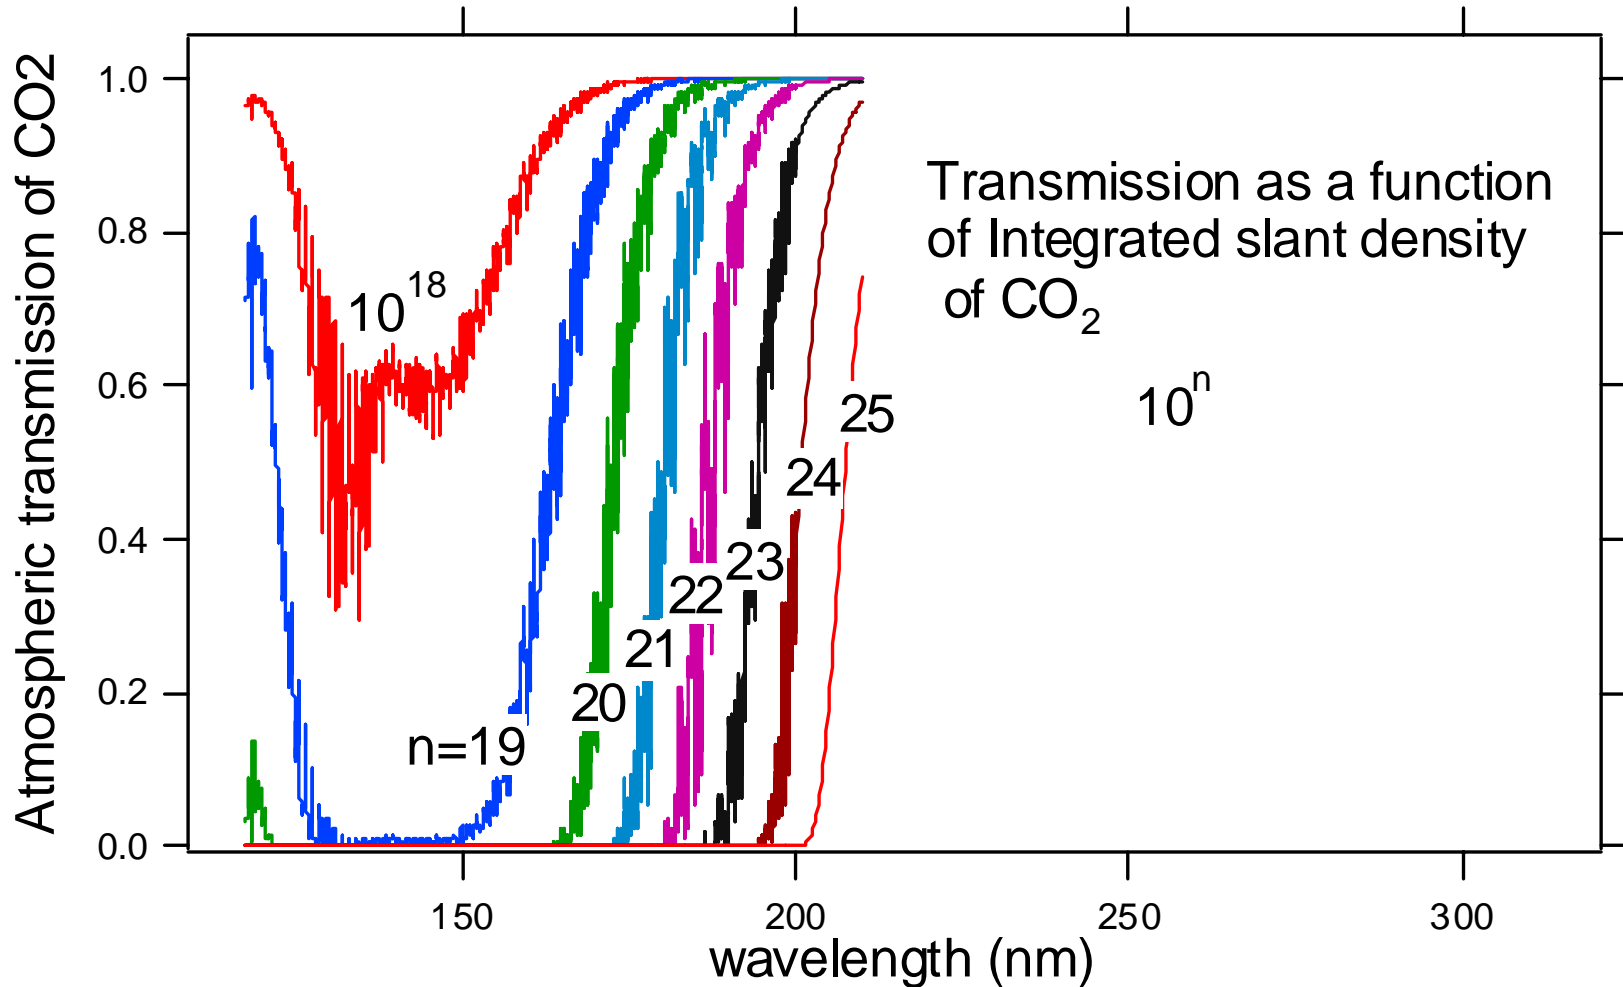

## Distribution in Local time and Latitude

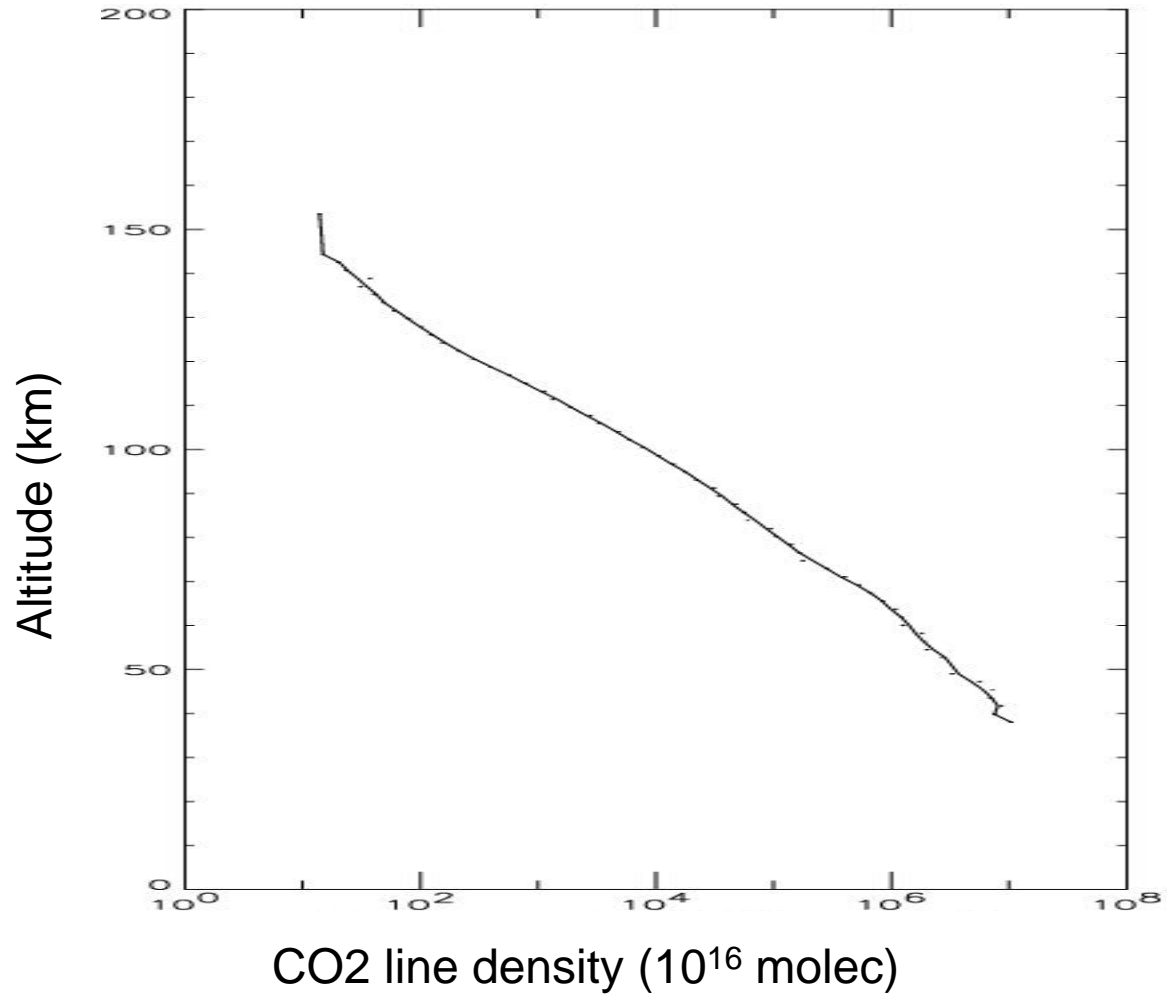

# Solar / Stellar occultation

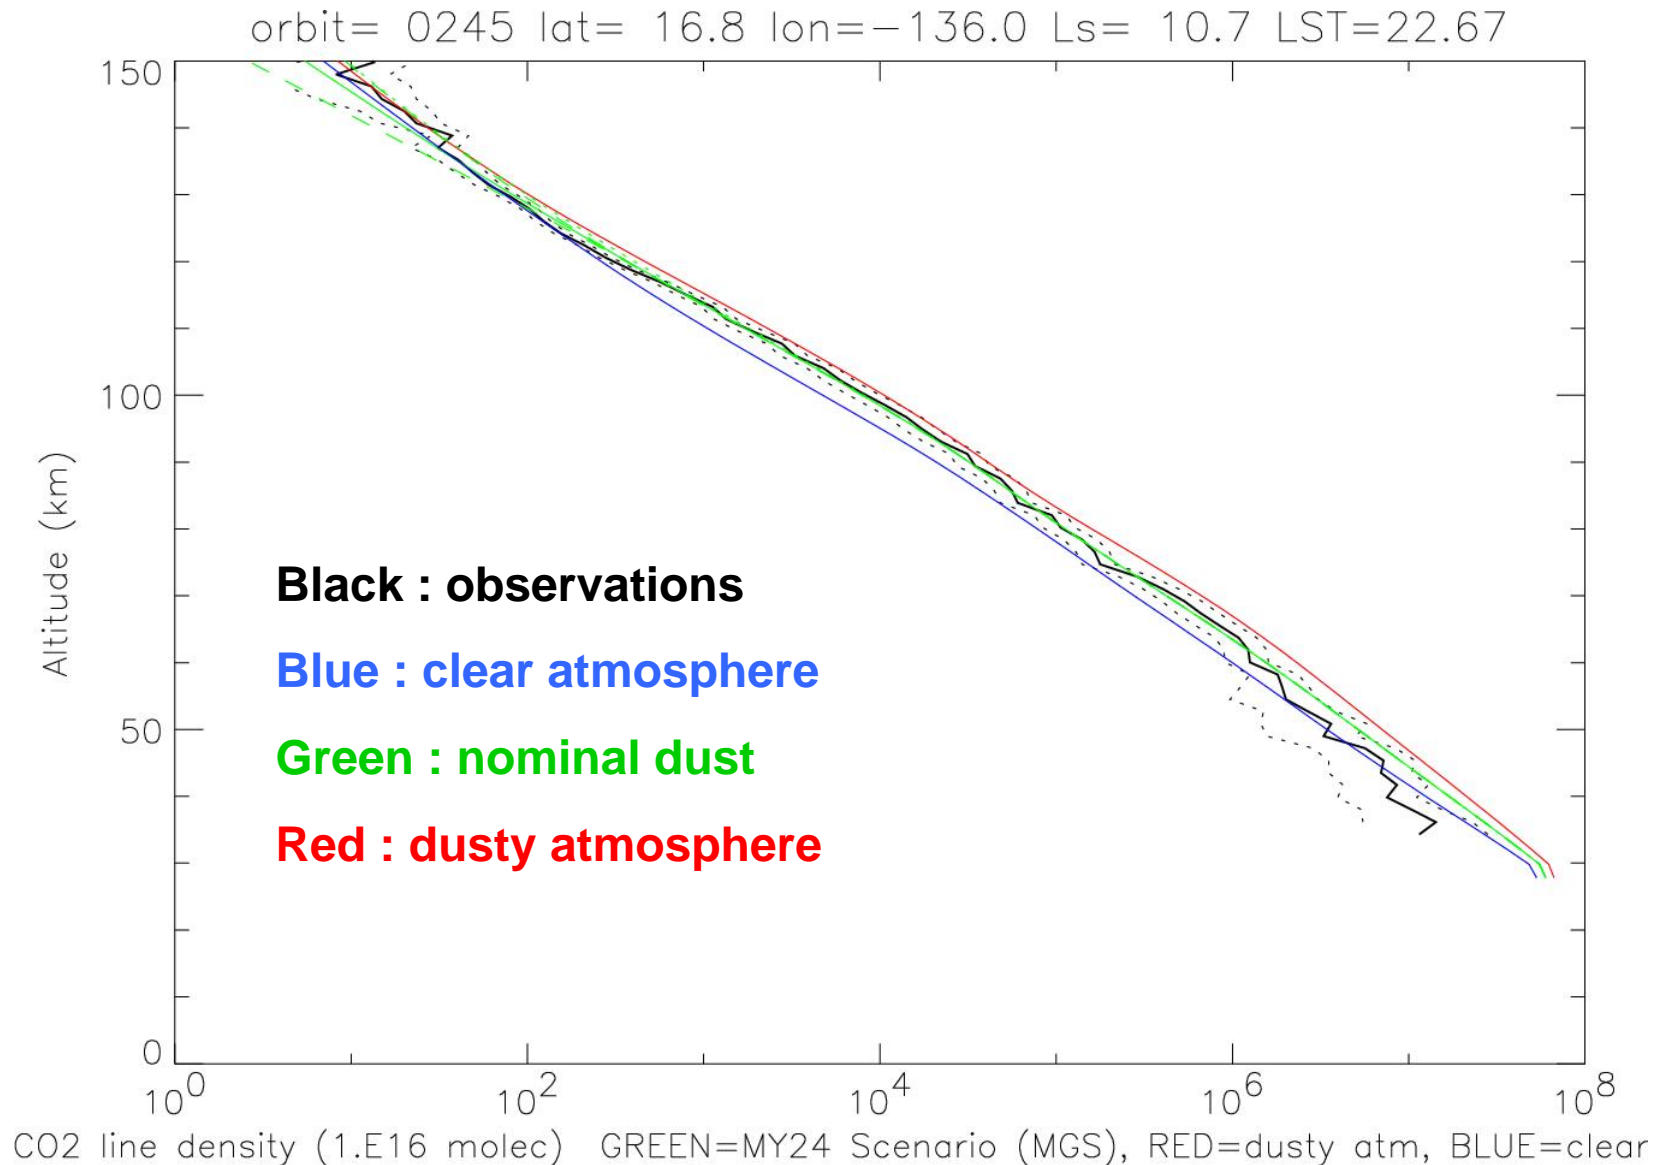

# Model Transmission as a function of wavelength of CO<sub>2</sub> (integrated slant density in molecules per cm<sup>2</sup>)

# CO2 line density

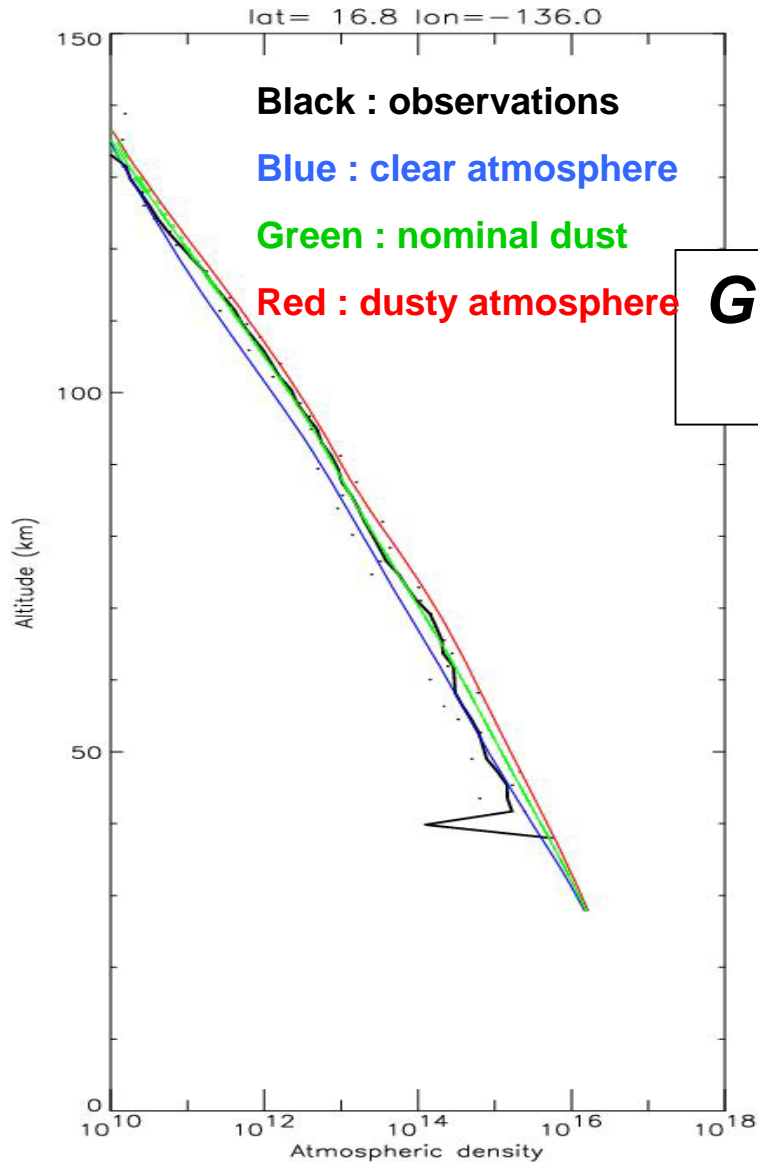

# In some cases : very good match with model prediction

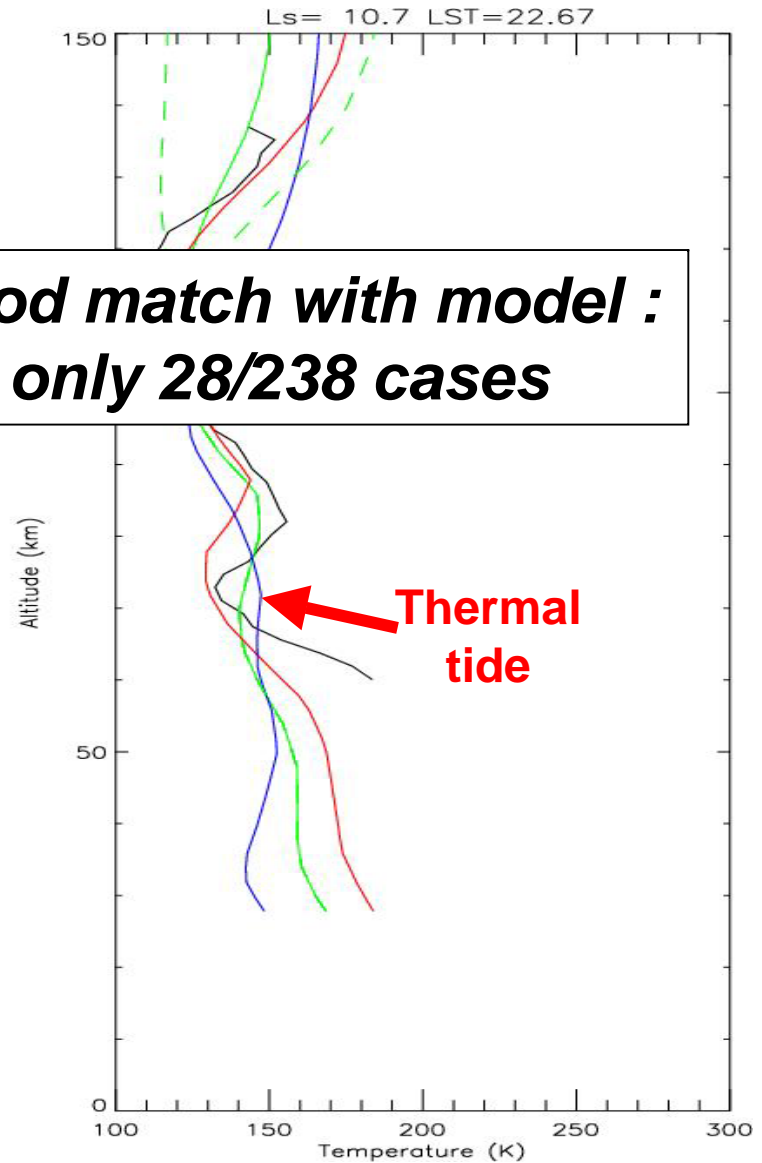

# Inversion of line density

Density

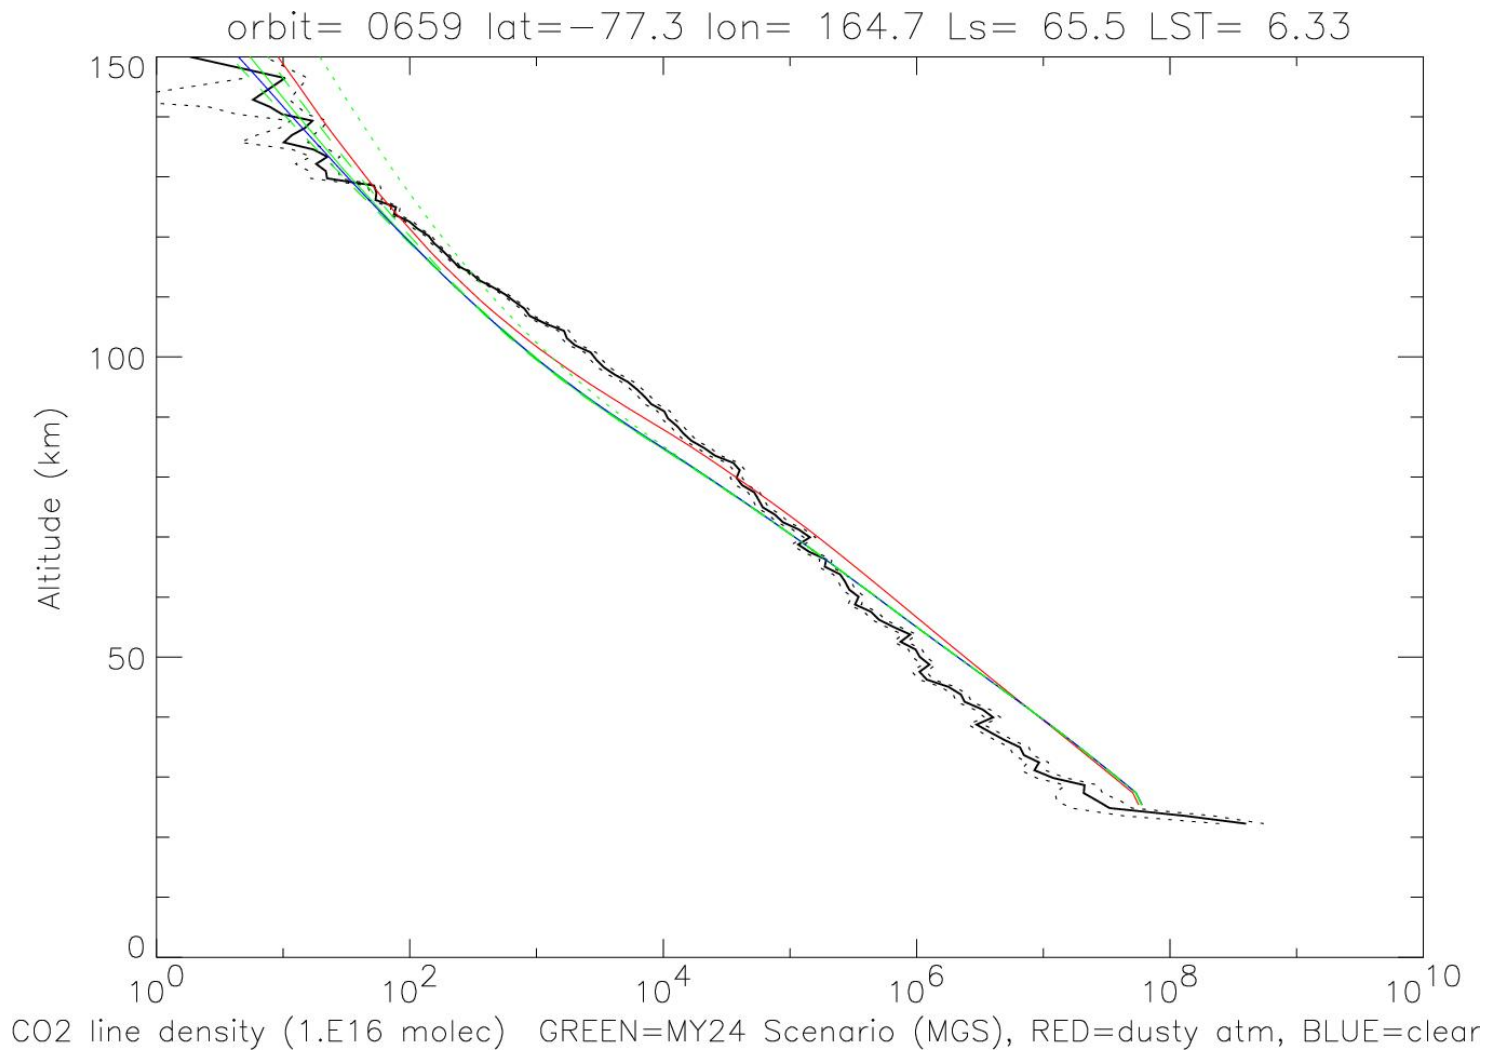

Temperature

**Good match with model :  
only 28/238 cases**

# A few cases :warmer, denser high atmosphere

# A few cases :warmer, denser atmosphere

## Density

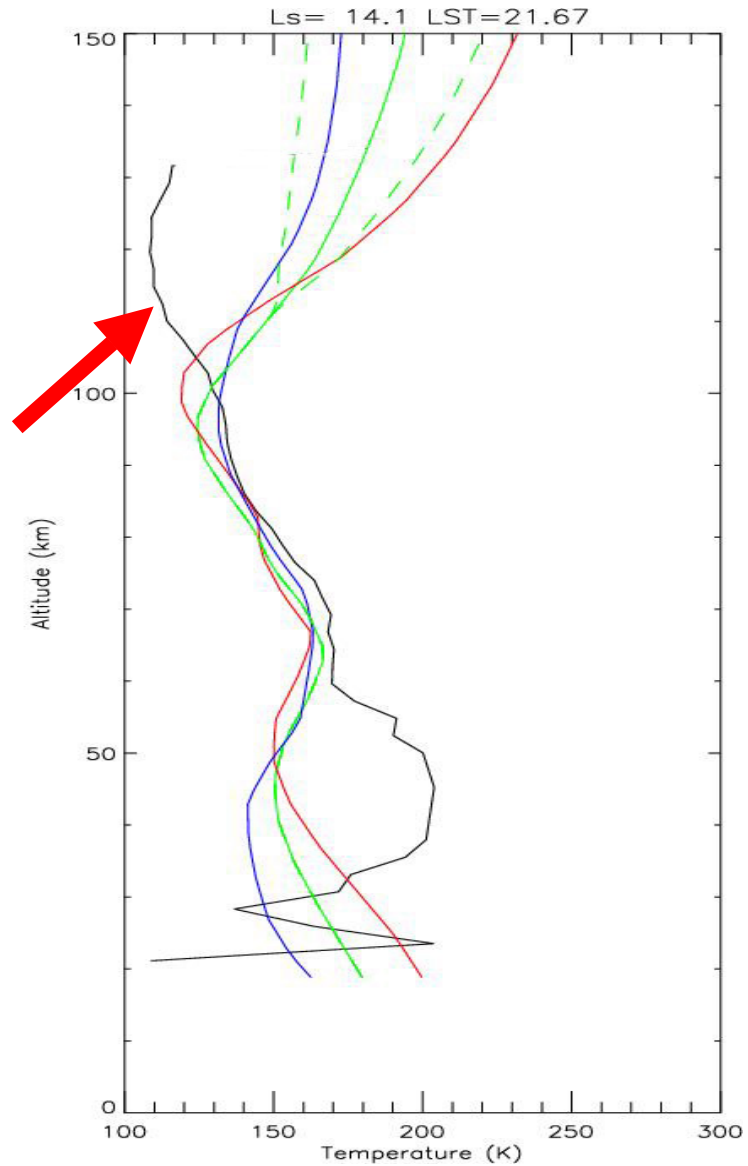

## Temperature

# Most cases : low density / cold atmosphere above

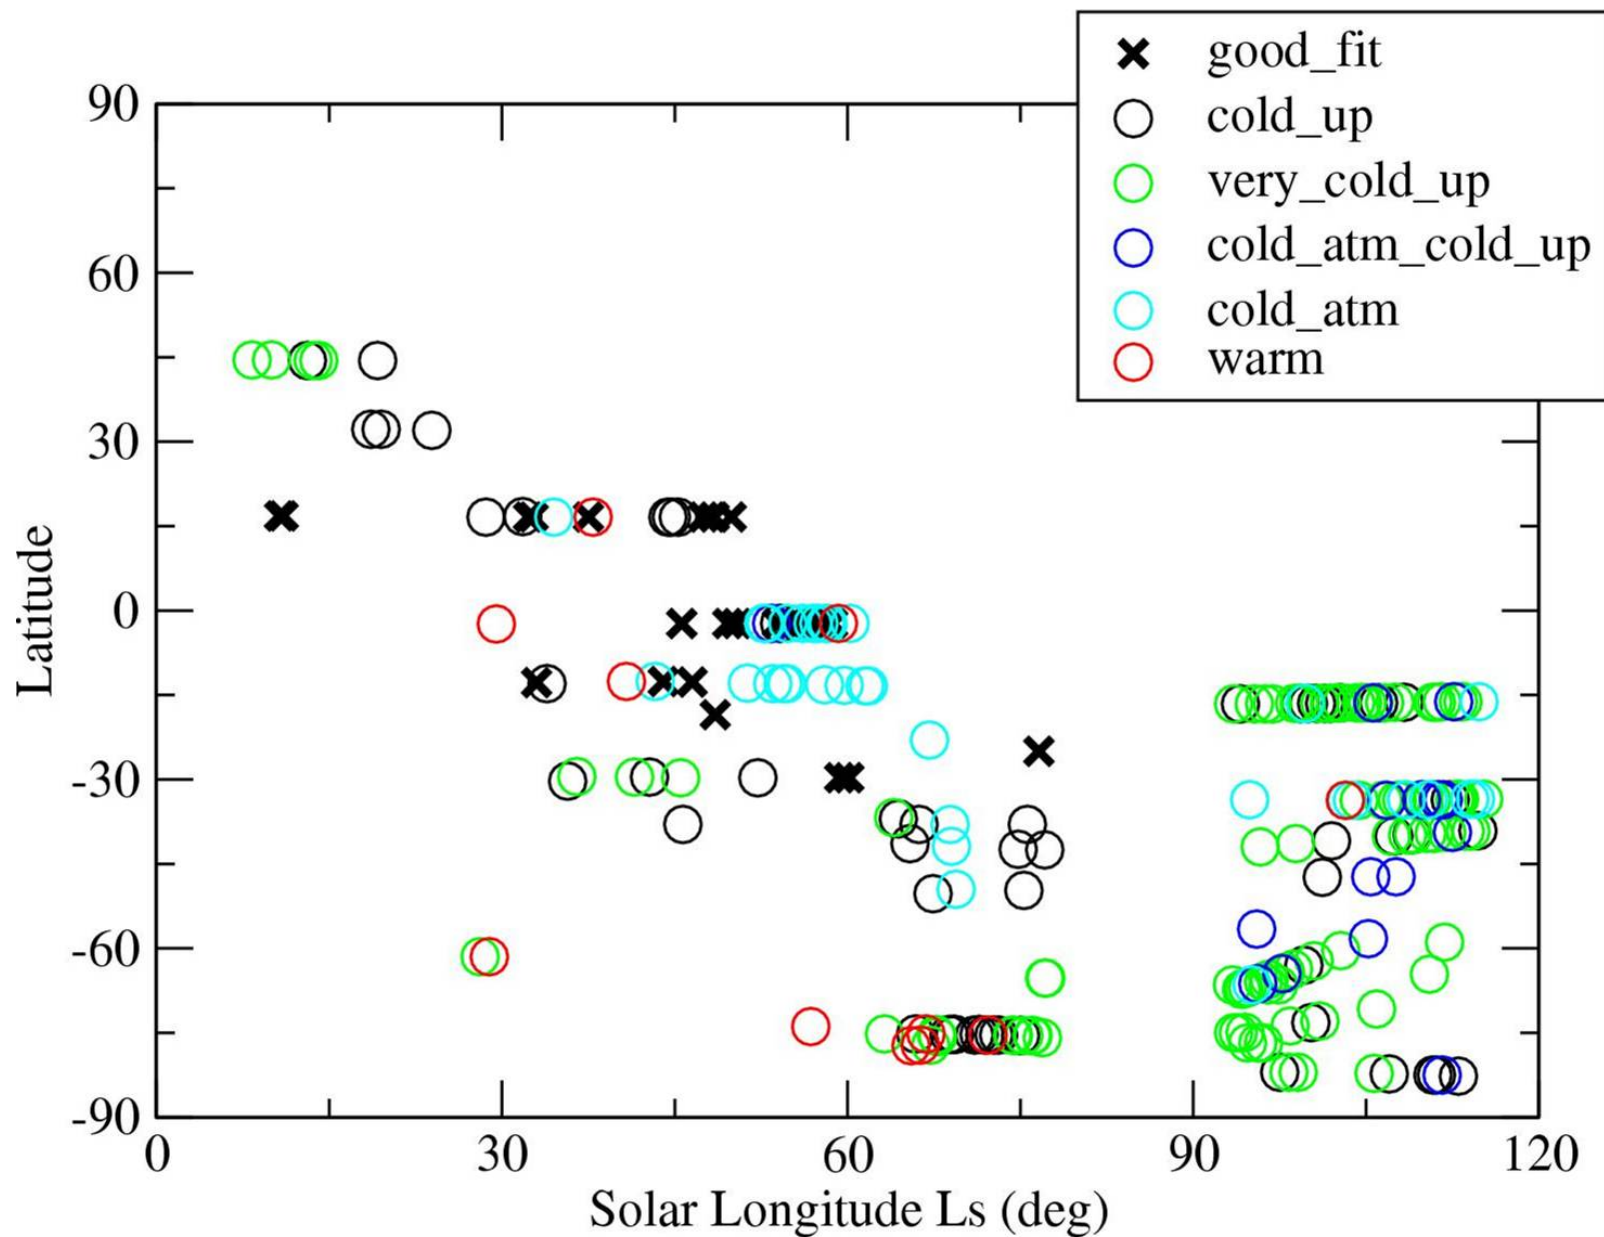

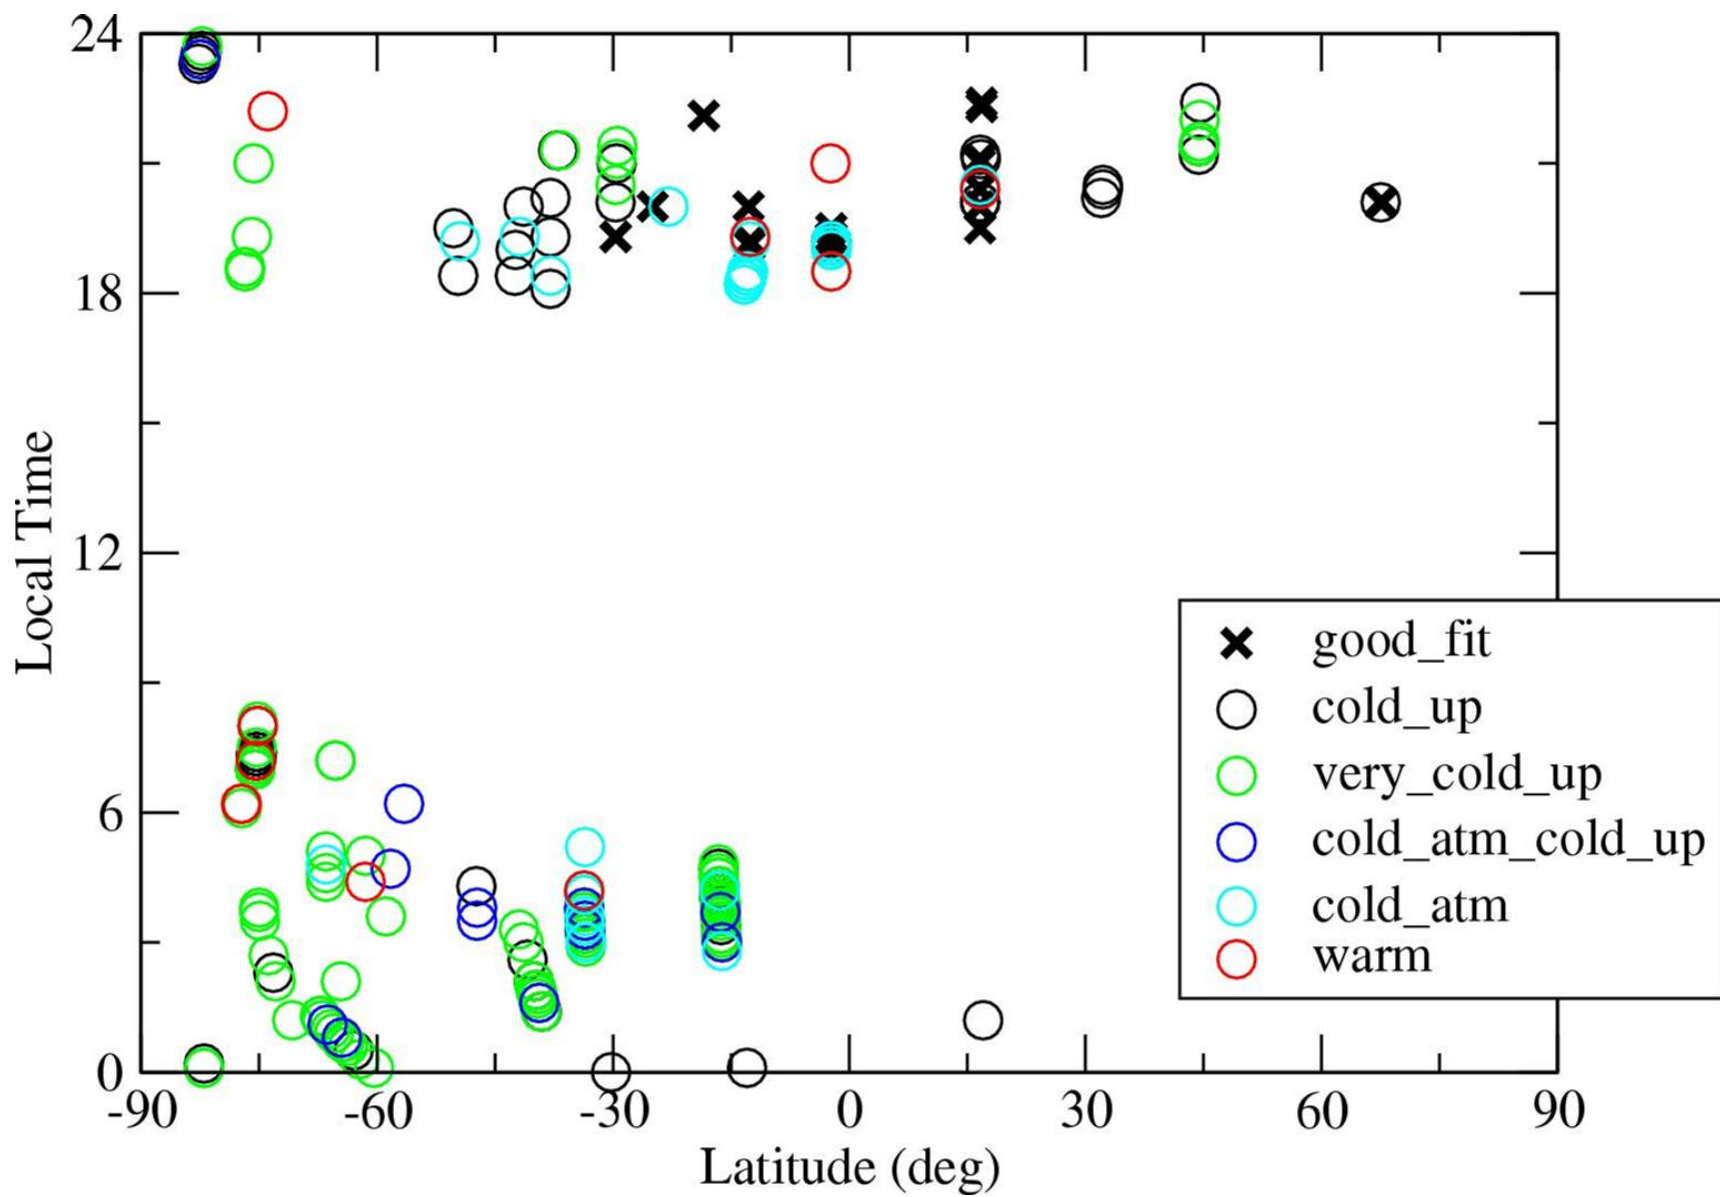

Most cases : low density / cold atmosphere above

# Trends in the characteristic of the observations – model disagreement

- Good fit : 12%
- Cold upper atmosphere : 25 %
- Very cold upper atmosphere : 38%
- Cold upper atm. + cold lower atm 6%
- Cold lower atm. : 14 %
- Warm atmosphere : 5%

# Why low density / cold temperature ?

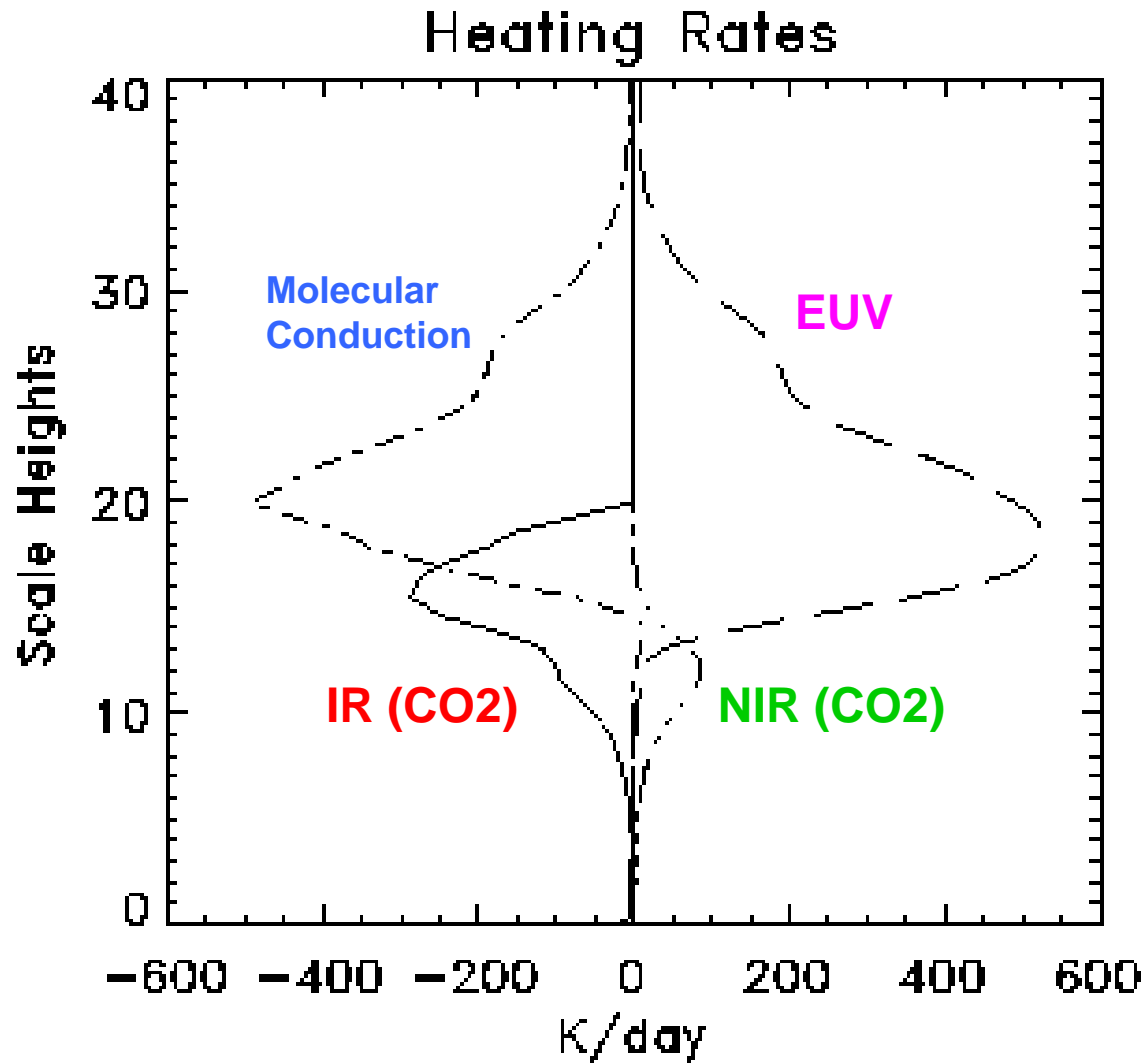

- Problem with data...
- Strong decrease of CO<sub>2</sub> mixing ratio above the homopause ? Unlikely
- Actual low temperature ?

⇒ Energy balance

# Why so cold ?

## Energy balance of the upper atmosphere

# Conclusions

- Hundreds of good quality profile of the Mars atmosphere. Work in progress:
  - CO<sub>2</sub> cross section poorly known at low temperature
  - Inversion must be improved
- If one believe the observations : upper atmosphere (> 100 km) much less dense or colder than expected.
