

# FORMATION OF OUR SOLAR SYSTEM

Dr. Björn J. R. Davidsson  
Jet Propulsion Laboratory,  
California Institute of Technology

# The Interstellar Medium

We are heading back 4.6 billion years in time...

Turbulent winds in the interstellar medium form filaments that condense to *starless cores*

These  $\sim 10,000$  AU $\star$  balls of gas and dust grains live for  $\sim 1$  million years before contracting due to gravity

$\star$  Average distance between Sun and Earth: 1 Astronomical Unit (AU) = 150 million kilometers

# Protostar formation

The starless core shrinks to  
 $\sim 100$  AU in 10,000 years  
and flattens

# The Solar Nebula

The protosun feeds on the accretion disk

It reaches its current mass in  $\sim 300,000$  years

A tiny disk of gas and dust remains: the *Solar Nebula*

# Presolar and locally produced grains

The Solar Nebula contained gas and sub-micrometer grains of silicate, sulfides, organics, and ice

# Coagulation – grains stick to each other

Small fractal aggregates  
form, then cm-sized *pebbles*

COSIMA, GIADA, MIDAS  
reveal aggregate size,  
structure, composition

# Formation of large trans-Neptunians

*Streaming instabilities:*

Gas and pebbles interact to create *pebble swarms*

Gravitational collapse  
form 100km-class *porous*  
bodies at  $t \sim 1$  million years

Mechanism stalls when  
 $\sim 10\%$  pebbles remain

# Processing of large bodies

Radioactive  $^{26}\text{Al}$  melts ice:

- Compaction, strength enhancement
- Loss of supervolatiles
- Liquid water changes olivine and pyroxene to *phyllosilicates*

Possible example: captured Saturnian satellite *Phoebe*

*Are comet nuclei collision fragments of such bodies?*

[3]

[4]

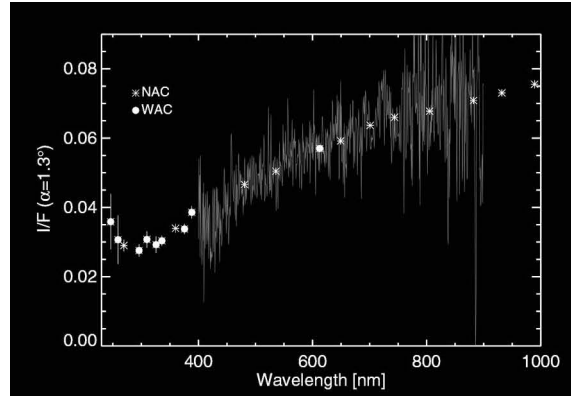

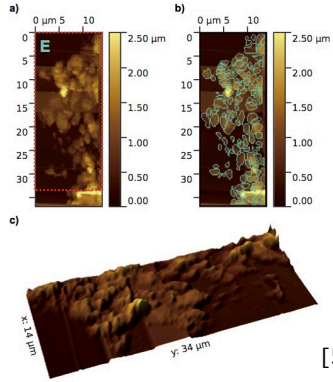

[3]

# Rosetta: Key discoveries I

## Rosetta says no!

- Very high porosity (RSI, OSIRIS, COSIMA, GIADA, MIDAS, CONSERT)
- No phyllosilicates (OSIRIS, VIRTIS)
- Weak strength (OSIRIS, Philae)
- Abundant supervolatiles (ROSINA, VIRTIS, MIRO, ALICE)

# Cometesimals form out of remaining pebbles

*Hierarchical agglomeration:*  
gradual growth by mergers

Meter-sized rather *dense*  
units form at  $\sim 30$  m/s

10-1000 meter *porous*  
units form at  $\sim 1$  m/s.

Small sizes:  $^{26}\text{Al}$  heat lost!

Porosity, supervolatiles survive

# Rosetta: Key discoveries II

Philae (CIVA, ROLIS)  
reveals structures  
on mm, cm, dm, and  
m levels.

MIRO: very low heat  
conductivity is another  
manifestation of high  
porosity

# Rosetta: Key discoveries III

## OSIRIS:

Goosebumps ( $\sim 3$  m) and positive relief features ( $\sim 300$  m) are potential evidence of hierarchical growth.

## CONSERT:

Building blocks smaller than  $\sim 10$  m.  
Porosity increases with depth over upper  $\sim 150$  m.

[9]

[9]

# Comet growth in the primordial disk

The solar nebula gas disappear  
at  $t \sim 3$  million years

Trans-neptunians growing to  
the size of Pluto stir the disk.  
Accretion velocities increase  
to a few  $\sim 10$  m/s.

Most cometesimals break  
up into their goosebump  
constituents?

# Comet growth in the primordial disk

Similarly-sized objects rarely collide in the solar nebula

Stirring in the primordial disk changes situation

Bi-lobed nuclei form in  
~ 25 million years

Comets avoid destructive collisions and survive undamaged.

# Rosetta: Key discoveries IV

Terraces reveal deep ( $\sim 600\text{m}$ ) layering, likely formed by a sedimentation process prior to the merger of two cometesimals into 67P/C-G.

# Relocation to current comet reservoirs

Primordial disk at 15-30 AU  
from the Sun, exterior to  
giant planets at 5-12 AU

Gravitational instability  
at  $t \sim 400$  million years moves  
giant planets to 5-30 AU region

Primordial disk disrupted.  
Kuiper belt, Scattered disk,  
Oort cloud form.

# Alternative scenarios

Did comet nuclei form during a late second episode of streaming instabilities?

*Revealing whether small planetesimals form through hierarchical agglomeration or streaming instabilities tells how the solar nebula functioned.*

Did comets collide violently with each other?

*Collision rates tell us the number of comets in the early solar system.  
That has direct implications for the amount of comet water and  
organics brought to Earth*

# Conclusions

Comet properties are shaped by their birth *environment*.

Understanding that *environment* is the key to understand planet formation, transport of water and organics to Earth.

Rosetta and similar spacecraft are necessary tools for advancing our knowledge about the early solar system
