The DNA of the Solar System

Asteroids are remnant of solids of the protoplanetary disk in which planets were formed

Dark (C, D) type asteroids \Leftarrow are the most primitive

Asteroid Spectra, Composition and number

Mean distance to Sun

The NEO population

NEOs offer many advantages:

- Accessibility
- Identified links to other small body populations
- DNA of the Solar System
- Great diversity of physical and compositional properties
- Hazard

Origin of NEOs

Asteroids from different regions of the Main Belt (MB) are injected into resonances which transport them on Earth-crossing orbits

A small fraction (6-8%) of NEOs come from Jupiter-family comets

Fast resonances: Main Belt Asteroids become rapidly NEOs by dynamical transport from a source region (in a few million years)

Four main sources of NEOs have been identified

- Main Belt (MB) asteroids injected into the 3/1 mean motion resonance with Jupiter
- MB asteroids injected into the v₆ secular resonance
- Outer Main Belt Asteroids (beyond the 3/1)
- Intermediate Mars-crossers
- Jupiter-family comets

The dynamics of bodies from each source has been investigated numerically in details and led to the determination of their distribution once in the NEO space (Bottke et al. 2002, Icarus 156, 399)

Example: likely origin of 1999JU3

From its current orbit:

a=1.19 AU, e=0.19, i=7.22°

8.37% chance of coming from the 3/1 Mean motion resonance with Jupiter (a=2.5 AU)

91.63% chance of coming from the v_6 secular resonance (a=2.26 AU)

⇒ Being a C-type (most numerous in the Outer belt) 1999JU3 may be linked to the Baptistina family, a C-type family close to v_6

Density plot of NEOs coming from the 3/1 resonance (red=large number, black=small number, white=none

A great diversity of sizes and shapes

433 Eros - 33 × 13 km NEAR, 2000

5535 Annefrank 6.6 × 5.0 × 3.4 km Stardust. 2002

2867 Steins 5.9 × 4.0 km Rosetta, 2008

25143 Itokawa 0.5 × 0.3 × 0.2 km Hayabusa, 2005 9969 Braille 2.1 × 1 × 1 km Deep Space 1,1999

253 Mathilde - 66 × 48 × 44 km NEAR, 1997

243 Ida - 58.8 × 25.4 × 18.6 km

Galileo, 1993

Dactyl [(243) Ida I] 1.6 × 1.2 km Galileo, 1993

951 Gaspra 18.2 × 10.5 × 8.9 km Galileo.1991

1P/Halley - 16 × 8 × 8 km Vega 2,1986

19P/Borrelly 8 × 4 km Deep Space 1, 2001 81P/Wild 2 5.5 × 4.0 × 3.3 km Stardust. 2004

9P/Tempel 1 7.6 x 4.9 km

Deep Impact, 2005

Note: only two asteroids have been visited so far, and are of the same type (S) No such information exist for a primitive (dark type) asteroid

Eros surface taken from 823 feets (NEAR)

Layer of fine regolith, 10-100 m depth 1 m to 100 m-size boulders

The two visited asteroids: both S taxonomic type and totally different surface properties

Itokawa surface: gravel, pebbles (Hayabusa)

Outer regolith layer with mean depth about 44 cm

Asteroid Mathilde 253

C-type low albedo (<0.1)

S-type

Asteroid Eros

 2.7 g/cm^{3}

Note: even two bodies of same spectral type can be very different!

S-type high albedo (> 0.15)

 1.3 g/cm^{3}

Asteroid Itokawa

Great diversity of structures

⇒Importance of bulk density estimate

 \Rightarrow Can tell us something about the collisional history of asteroids

In-situ observations and modelling can improve our understanding of formation processes of NEOS

Gravitational phase of a disruption

Michel P., Benz W., Richardson D.C. 2001. 2002, 2003, 2004a, b Michel P. 2006, Lecture Notes in Physics Michel P. 2009, Lecture Notes in Physics Disruption by impact of a large asteroid: fragmentation phase computed with properties of terrestrial rocks; ⇒would benefit from the knowledge of real properties of an asteroid thanks to sample analysis!

Surface and internal properties: crucial information for hazard mitigation

• Example: Mission Don Quijote: phase A studies at ESA (final presentation: 17-18 Avril 2007)

The momentum transfer efficiency highly depends on the surface properties (e.g. porosity) and internal properties (e.g. Monolithic vs. Rubble pile)

So far, we have no information at all concerning a dark type NEO

Conclusions

- NEOs are ideal targets for a sample return mission:
- Easily accessible
- The likely source region of an object can be identified
- Have kept (at least part of) the memory of the Solar Nebula in which planets formed
- Primitive ones contain information of great interest for exobiology
- Can tell us about the geological (and other) processes that they undergo during their history (e.g. reaccumulations, seismic shaking)
- Represent a hazard which requires information on their internal and surface properties

And finally, high level of public outreach!
