Instrument design ↔ science requirements

Standard ETC approach

- instrumental parameters
 - Exp. Time, effective area, throughput, electronic dark current and ron,...
- source characteristics,
 - Flux, extension, spectral type
- Background
 - Sky emissivity

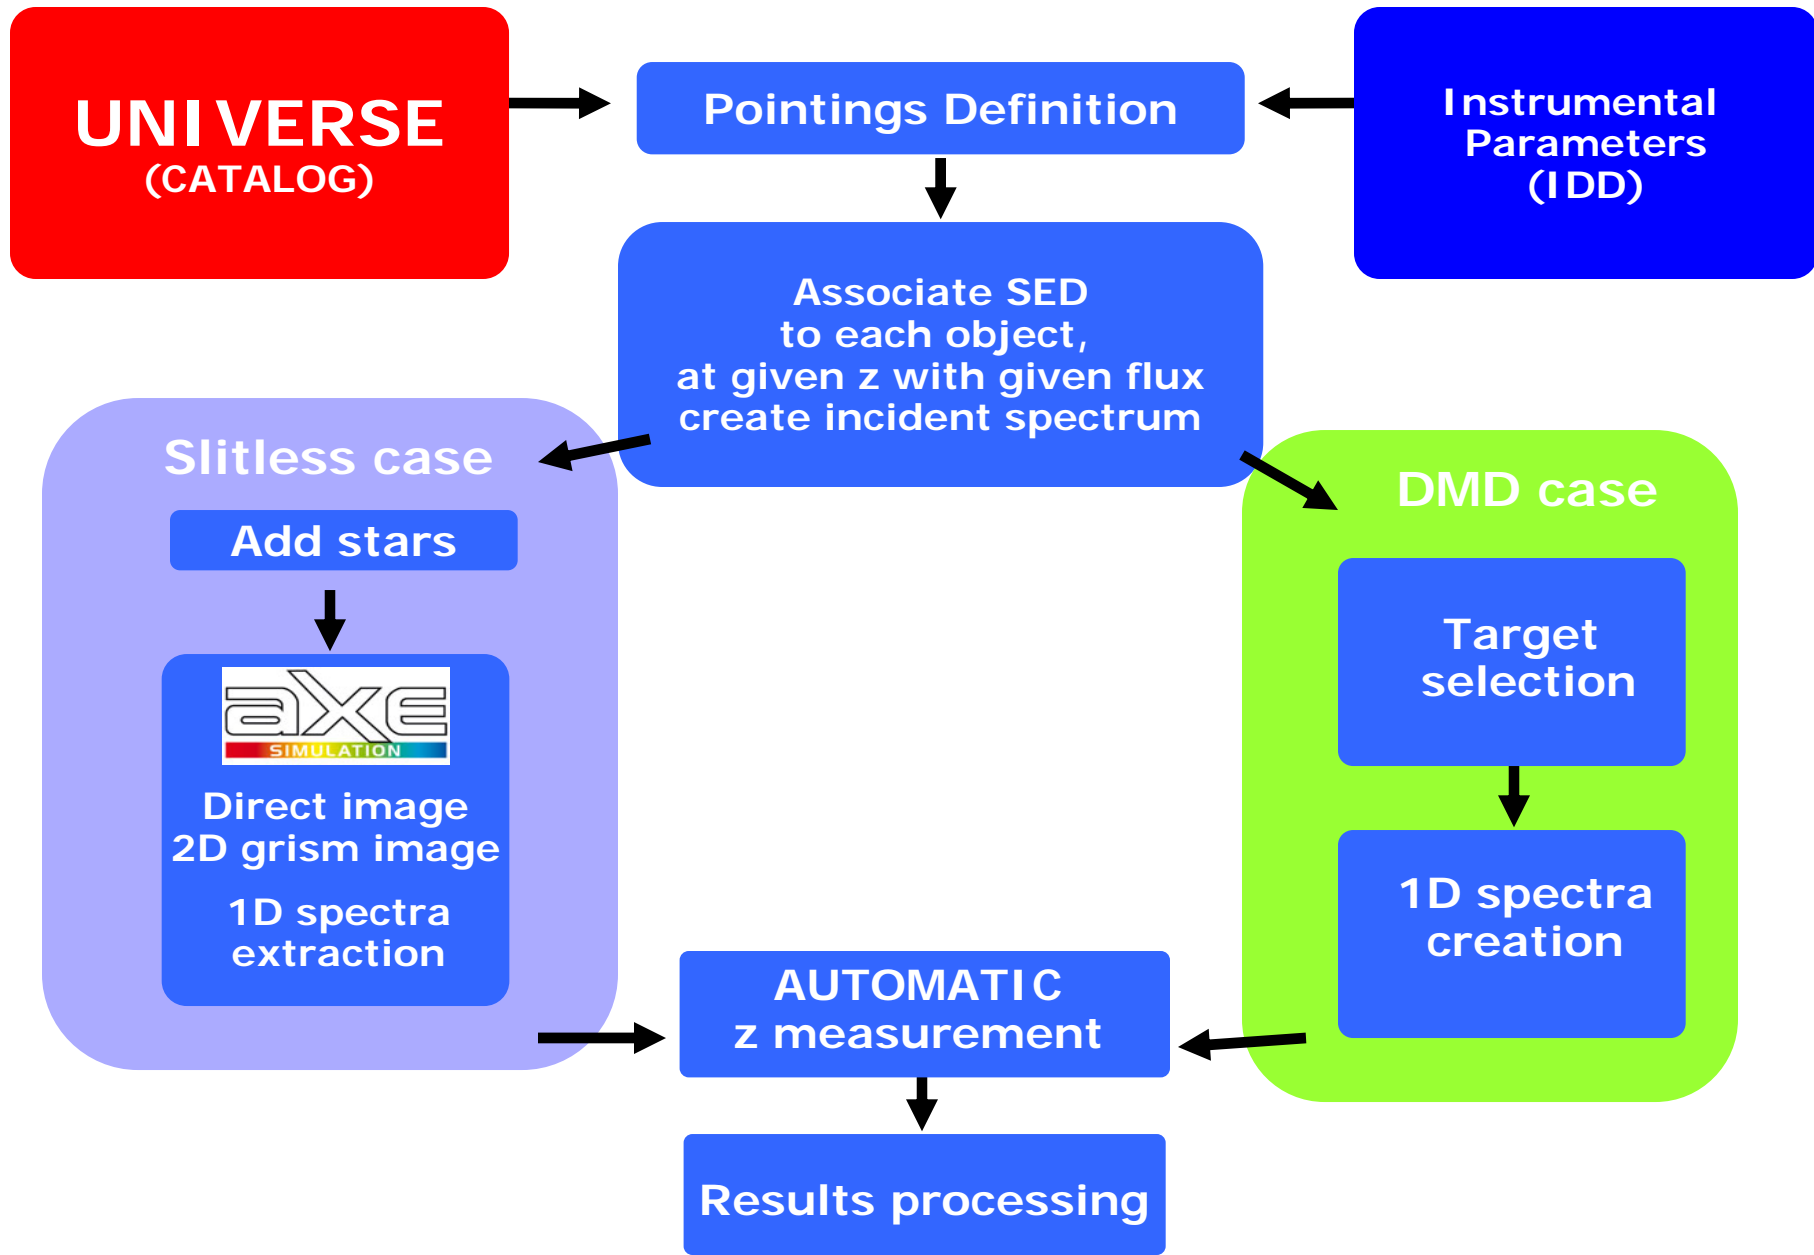

$$S/N = \frac{S}{\sqrt{\text{Var}(S) + \left(1 + \frac{1}{n_s}\right)(\text{Var}(B) + \text{Var}(D))}}$$

- **ASSUME** $s/n > x \Rightarrow$ redshift measured
- convolution with galaxy counts and redshift distribution to get to total survey yield,
- SLITLESS: does not take into account confusion

Full End to End approach: from mock catalogs to redshift measure, via simulation of spectra and redshift measurement

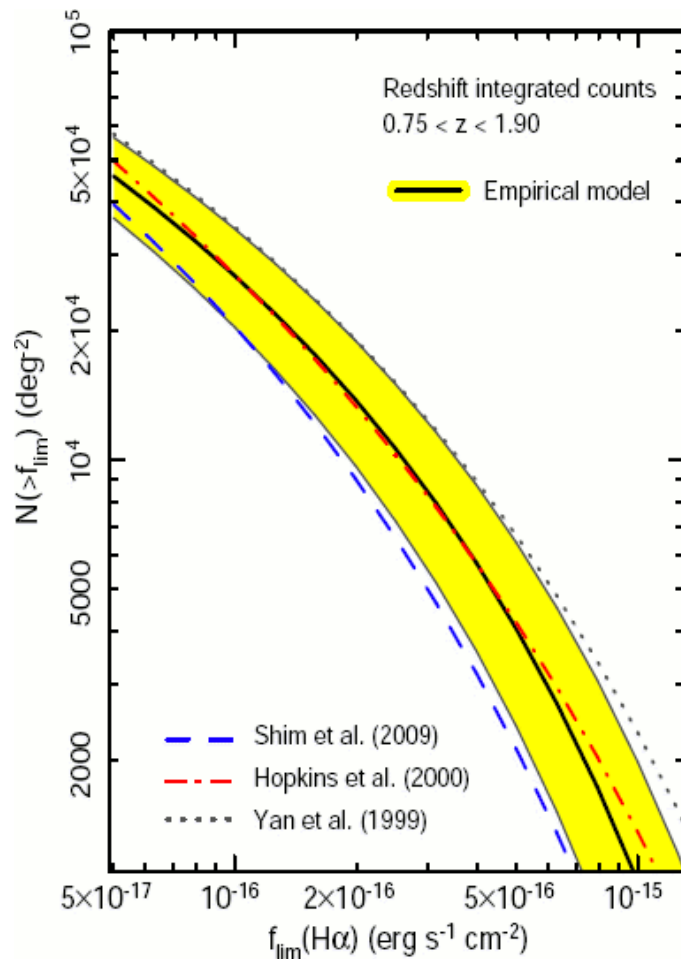

Full end to end simulations

Input counts and dN/dz of H α emitters

- Geach et al. 2009, MNRAS accepted : Latest empirical data to model an evolution LF of H α emitters to $z \sim 2$
- Reproduce slitless (Nicmos) + narrow-band NIR surveys results (Yan 99, Hopkins 00, Shim 09, Geach 08)
- Best current estimates of $N(>F_{H\alpha})$ and dN/dz , but still suffers from $\sim 25\%$ uncertainty.

End-to-end Sky Simulations

aXeSim simulations

Direct Image

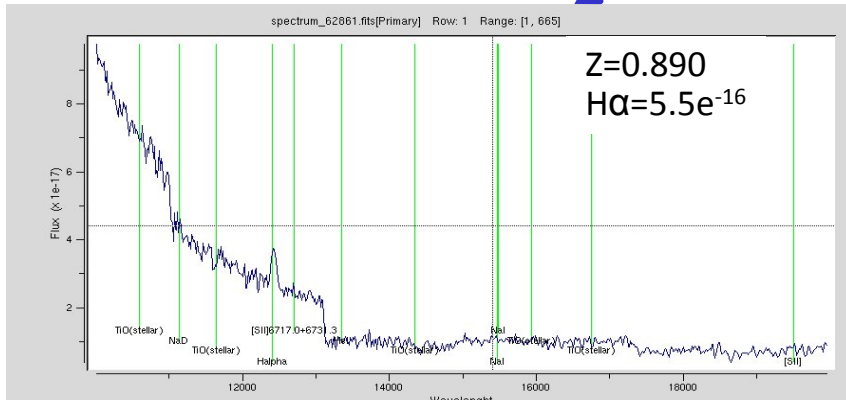

Slitless Image

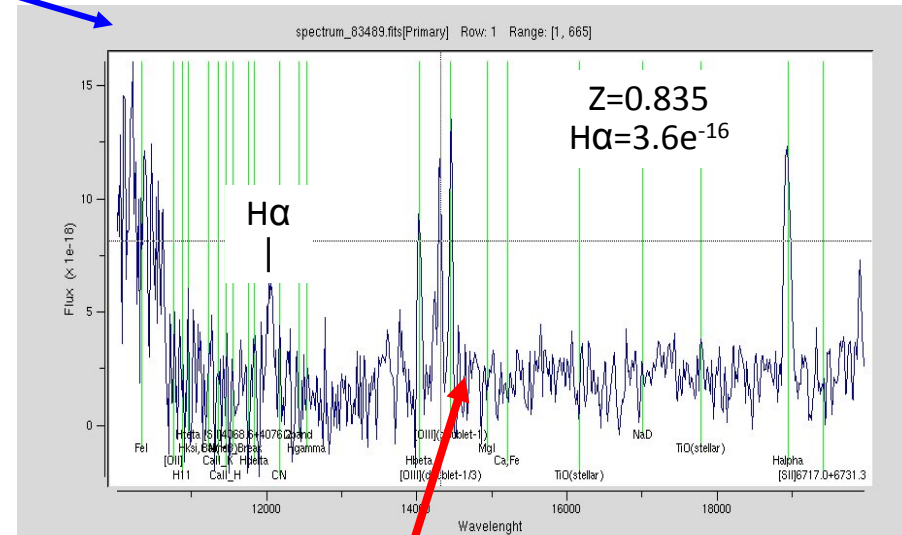

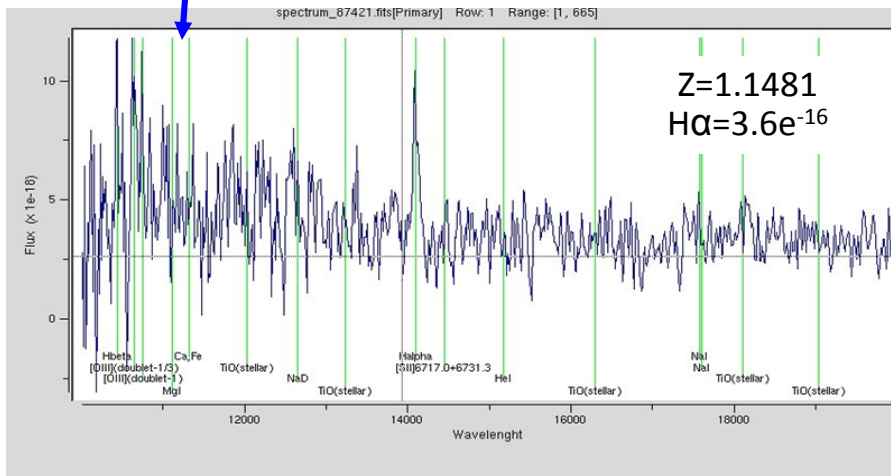

$5-10 \times 10^{-16}$

2-4 x10⁻¹⁶

Contaminated, wrong redshift

DMD case

- no contamination,
 - no need to simulate 2D image
- need to take into account target sampling
 - SPOC (Bottini et al. 2005), adapted to E-NIS

30,000 galaxy/sq.degree
simulations over 1 square degree
sampling=35%

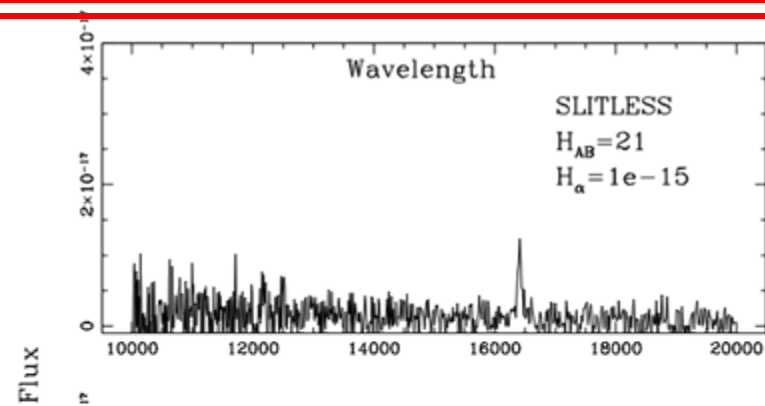

EUCLID DMD case: expected surface density and redshift distribution of galaxies to the magnitude limit $H_{AB}=22.0$

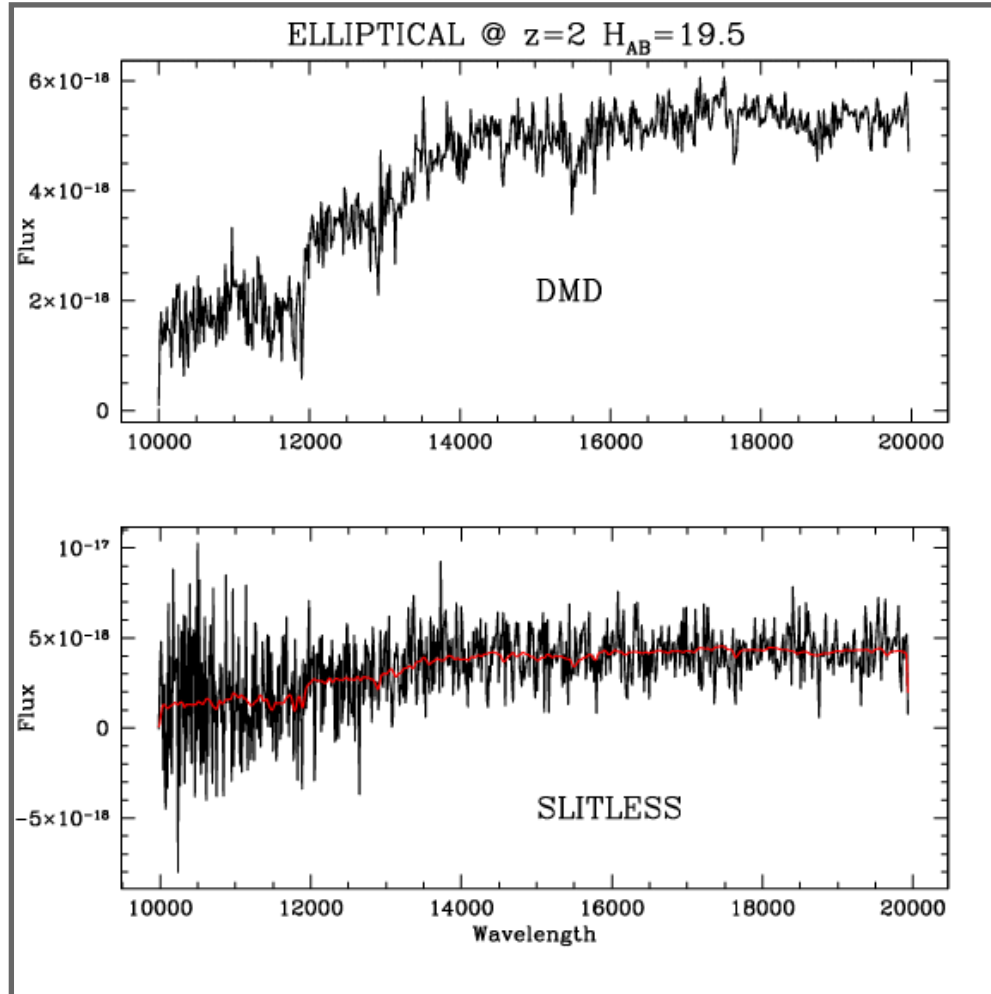

Contributions by: C. Baugh, F.-J. Castander, M. Cirasuolo, E. Daddi, O. Ilbert, H.J. McCracken, L. Pozzetti, P. Rosati, M. Scodreggio, A. Cimatti

Prepared by: G. Guzzo and G. Zamorani
February 27, 2009 (v3.0)

Empirical number counts and dN/dz to $H=22$ based on a combination of COSMOS, GOODS, UKIDSS-UDS

- Require catalog with ALL sources (E included), down to a given magnitude
 - Cosmos Mock Catalog, Jouvel et al. 2009

Accuracy and reliability

- Redshift automatically measured with EZ (used for VVDS and zCosmos)
- Not only redshift, but “accurate” and reliable
- Reliability computed on the basis of
 - **Line S/N**
 - **Presence of other “expected” lines**
 - **Continuum (DMD only)**
 - **Considered “successful” only redshifts with highest reliability**

σ_z	Slitless	DMD
Accuracy (R=500)	10^{-3}	$<10^{-3}$
$\sigma_z/(1+z)$		
Reliability	85%	90%

The problem of contamination: Multiple roll angle approach

0

45

90

135

4 exposures at different orientations on sky

Not exciting results, due to high galaxy density

Requires further investigation on best combining strategy

The multiple-filters approach

Strong decrease of the sky background

Similar S/N ratio for emission line

Spectra are "shorter" (170 pix vs 670 pix) (less severe spectral confusion)

10000-12500

12500-15000

15000-17500

17500-20000

1 sq. deg simulated per configuration

Success rate increase

4 roll 4 filters
+7% +15%

Multi grism approach gives better results

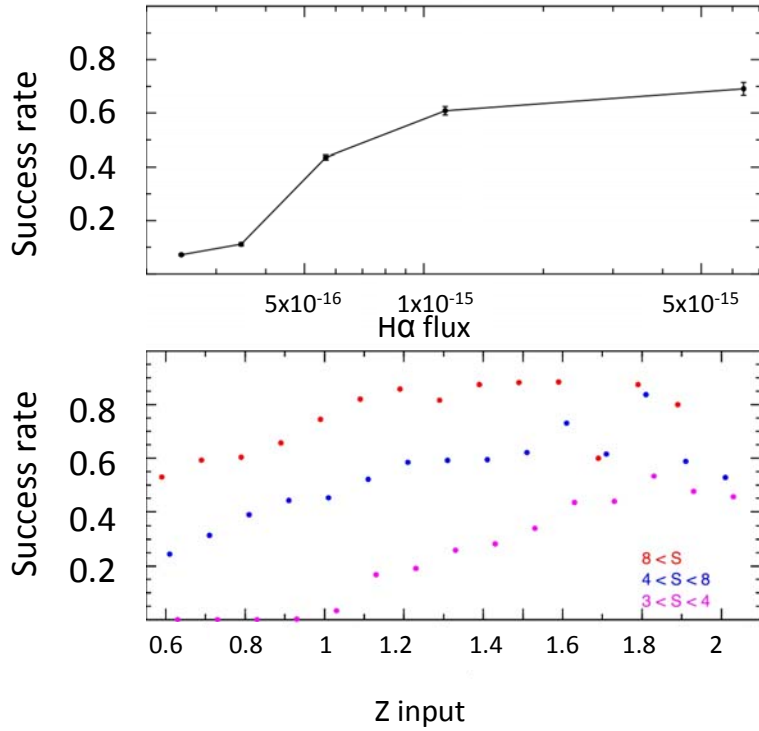

Multi roll approach requires deeper investigation

ON GOING

Success rate

$\epsilon(F, z)\epsilon = \text{reliable redshifts (>85\%)} / \text{Total number of sources}$
2 sq. degrees ~ 60000 galaxies

Slitless success rate

DMD success rate

	SLITLESS CASE (single exposure)	DMD case
Survey limit	3e-16 erg/cm2/sec/A	H=22
Explorable z range	0.5-2	0.-2
Target sampling rate	100%	35%
Z success rate	30-60%	80%
Z accuracy	1.e-3	5.e-4
Zyeld/sq deg	~2700	~8400
Mission yield (5 years)	~6.5×10⁷	~1.5×10⁸
	only star forming galaxies smaller survey volume	all galaxy types larger survey volume FoM ~ 2-2.5 larger

Additional Science Cases: all OK with DMD, only some with slitless

Summary

- end-to-end simulations important to make sound predictions on global survey yield, especially in Slitless mode
- Current simulations can (and will) be improved
- **Slitless allows to fulfill main science goal**
- DMD based survey more powerfull
